NJIT CAMS Technical Report:
Mixed-mode oscillations in single neurons *

Definition

Mixed-mode oscillations (MMOs) in neuronal systems are oscillatory patterns of activity consisting of subthreshold (or membrane potential) oscillations interspersed with action potentials (or spikes).

Detailed Description

Introduction

Rhythmic oscillations in the theta (4-12 Hz) and gamma (30 - 100 Hz) frequency bands have been recorded in the hippocampus and the entorhinal cortex, and have been implicated in cognitive processes including memory, spatial navigation and sleep (Buzsáki 2002, 2006; Kahana et al. 1999; O’Keefe and Recce 1993; Traub and Whittington 2010; Buzsáki and Wang 2010; Engel et al. 2003; Fries 2009; Singer and Gray 1995; Bragin et al. 1995; Montgomery and Buzsaki 2007). These network oscillations emerge from the cooperative activity of the participating neurons and network connectivity.

Intrinsic subthreshold (membrane potential) oscillations (STOs) and MMOs at theta and gamma frequencies have been observed in various neuron types (Alonso and Llinás 1989; Dickson et al. 2000b,a; Leung and Yim 1991; Fransén et al. 2004; Schmitz et al. 1998; Yoshida and Alonso 2007; Bourdeau et al. 2007; García Munoz et al. 1993; Llinás et al. 1991). MMOs have been most notably investigated in stellate cells in layer II of the medial entorhinal cortex (Fransén et al. 1998; Fernandez and White 2008; Giocomo et al. 2007; Yoshida and Alonso 2007).

*To be published in the Encyclopedia of Computational Neuroscience
Several models have been used to investigate MMOs (Wang 2002; White et al. 1998; Fransén et al. 2004; Acker et al. 2003; Rotstein et al. 2006, 2008; Jalics et al. 2010; Medvedev and Cisternas 2004; Dorval and White 2005; Brøns et al. 2008; Desroches et al. 2012; Morin et al. 2010). These models focus on the role of the ionic currents in shaping the MMO patterns (generation of STOs and the onset of spikes) or the dynamic mechanisms that give rise to MMOs.

The functionality of MMOs is still a matter of discussion. STOs have been argued to function as a timing device (Lampl and Yarom 1993) and to play a role in spatial navigation (Giocomo et al. 2007). While action potentials (or spikes) are the basic neuronal signaling mechanism (Johnston and Wu 1995; Koch 1999; Dayan and Abbott 2001; Ermentrout and Terman 2010), the interspersed STOs in the MMO patterns (Figs. 1 and 2) may help create a time scale at which information is effectively communicated among neurons.

**The structure of MMO patterns**

Typically, a MMO cycle consists of a small amplitude oscillations followed by L spikes (or vice versa). The notation $L^s$ is customarily used to described these patterns (Desroches et al. 2012; Brøns et al. 2008) (and papers therein). MMO patterns can be regular (Figs. 1-A and -B) or irregular (Fig. 1-C). In turn, regular MMO patterns can be uniform, where the sequence $L^s$ describes the MMO patterns in their entirety (Fig. 1-A), or non-uniform, where MMO cycles consists of sub-cycles described by sequences $L_1^s - L_2^s - \ldots - L_N^s$ (for some integer $N$) (Fig. 1-B). Irregular MMO patterns can be either stochastic (Fig. 1-C) or chaotic (not shown).

The occurrence of $L^0$ cycles (for $L > 1$) embedded in MMO patterns, with two or more consecutive spikes with no interspersed STOs (Figs. 1-B2, B5 and -C), is customarily referred to as spike clustering (Fransén et al. 2004; Alonso and Klink 1993; White et al. 1998; Serafin et al. 1996; Desmaisons et al. 1999; Wang 2002; Muratov and Vanden-Eijnden 2008; Kuske and Borowski 2009). The inter- and intra-spike frequency may belong in the same frequency range or not depending on the neuronal type and other parameter values.

**Dynamic mechanisms of generation of MMOs**

The generation of MMO patterns requires the coordinated action of various mechanisms: (i) a mechanism for the generation of STOs, (ii) a spiking mechanism, including the onset of spikes and the description of the spiking dynamics, and (iii) a return mechanism from the spiking regime back to the subthreshold regime.

The minimal models able to generate intrinsic oscillatory behavior are 2D and involve the dynamics of the voltage $v$ and a recovery variable ($w$) (Rinzel and Ermentrout 1998; Rinzel 1985; Ermentrout and Terman 2010; Rinzel and Ermentrout 1998; Ermentrout and Kopell 1998; FitzHugh 1961; Nagumo et al. 1962). These models may generate either STOs (Fig. 3-A) or spikes (Fig. 3-B) but not MMOs. MMO patterns require an additional mechanism that describes the dynamic transition between these two regimes. This mechanism may be provided by an external input (non-autonomous system), such as in certain cases of the slow passage through a Hopf bifurcation (Holden and Erneux 1993; Baer et al. 1989) and the patterns resulting from oscillatory forcing (Barnes and Grimshaw 1997; Shimizu et al. 2012), or by an additional dependent variable (autonomous system) (Fig. 3-C) as in the 3D canard phenomenon (Wechselberger 2005; Brøns et al. 2006).
The minimal models that are able to generate intrinsic MMOs are nonlinear, 3D and involve multiple time scales. The prototypical example is the 3D extended version of the FitzHugh-Nagumo (FHN) model (FitzHugh 1961; Nagumo et al. 1962) (Fig. 3) describing the dynamics of the voltage $v$ and two gating variables ($w$ and $z$) with linear dynamics. Models of FHN type are caricature models, but they capture the basic dynamic properties observed in detailed biophysical (conductance-based) models.

In the example presented in Fig. 3 all the MMO mechanisms are described by the same model. The generation of STOs (Fig. 3-A3) and the onset of spikes (Fig. 3-B3) are governed by the locally parabolic portion of the $v$-nullcline, near its minimum. The spiking dynamics and the return mechanisms are primarily governed by the right and left branches of the $v$-nullcline respectively (Fig. 3-A2). The abrupt transition from STOs to spikes is due to the 2D (Figs. 3-A and -B) and 3D canard phenomena (Figs. 3-C) (Krupa and Szmolyan 2001; Wechselberger 2005; Brøns et al. 2006). The locally parabolic nonlinearity at the minimum of the $v$-nullcline and the time scale separation between $v$ and the remaining dependent variables are key for these mechanisms.

Higher dimensional models provide the necessary flexibility for the generation of more complex MMO patterns. Typically, in these models each mechanism (e.g., STOs, spikes) is described by a different, lower-dimensional regime (Rotstein et al. 2006).

Generalizations of the integrate-and-fire model to include 2D linear subthreshold dynamics (Izhikevich 2001; Richardson et al. 2003; Rotstein 2013) are able to produce MMOs provided the fixed-point of the underlying (subthreshold) 2D linear system is an unstable focus (Rotstein 2013). (Stable foci are possible in the stochastic case.) These models are referred to as STO-F models (STO-and-fire models) (Rotstein 2013). The mechanism of spike generation consists of a voltage threshold ($V_{th}$) and “artificial spikes”: spikes are added manually when the voltage $V$ crosses $V_{th}$. The return mechanism consists on the manual reset of $V$ and $w$ to predetermined values $V_{rst}$ and $w_{rst}$ after a spike has occurred. STO-F models with constant values of $w_{rst}$ generate regular uniform 1s MMO patterns (Fig. 1-A) where the number of STOs per cycle depends on the model parameters. The generation of regular non-uniform MMO patterns requires a return mechanism where at least one reset value (either $V_{rst}$ or $w_{rst}$) is not constant, and depends, for instance, on the number of consecutive spikes within some range (Fig. 1-B).

Generalizations of the integrate-and-fire model to include 2D or 3D nonlinear subthreshold dynamics, such as the reduced medial entorhinal cortex layer II stellate cell model (Rotstein et al. 2006) and extensions of the quadratic-integrate-and-fire models (Izhikevich 2001, 2006; Rotstein et al. 2006, 2008; Jalics et al. 2010), typically have a parabolic-like $V$-nullcline in the subthreshold regime and the gating variables have either linear or sigmoidal nullclines (Izhikevich 2001, 2010; Rotstein et al. 2006). These models are able to generate STOs provided the fixed-point in the subthreshold regime is a focus. In addition, these models describe the onset of spikes, but not the spiking dynamics. The voltage threshold $V_{th}$ indicates the occurrence of spikes, which are added manually. (Note that $V_{th}$ is not a part of the spiking generation mechanism.) The voltage and possibly the gating variables are reset after a spike has occurred (return mechanism). In principle, MMOs are possible when the subthreshold dynamics are 2D provided the reset point ($V_{rst}$, $w_{rst}$) is close enough to the fixed-point and the latter is unstable, thus generating a spiraling out solution. However, for biophysically plausible situations, this condition is not satisfied, and an additional subthreshold variable ($z$) is required to govern the dynamic transition from STOs to spikes (Fig. 2). The slow component of the h-current plays this role in the stellate cell model mentioned above.
(Rotstein et al. 2006, 2008), while a persistent sodium and the fast component of the h-current are enough to generate STOs.

The mechanisms of generation of MMOs in conductance-based models when different sets of ionic currents govern the dynamics of the subthreshold and spiking regimes are more difficult to analyze due to their high dimensionality. There are circumstances where the dynamics for different regimes can be treated separately by using reduction of dimensions methods (Rotstein et al. 2006).

The mechanism of generation of MMOs crucially depends on the mechanism of transition from STOs to spikes. Several mechanisms have been described in the literature (Guckenheimer et al. 1997; Wechselberger 2005; Guckenheimer 2008a,b; Krupa and Wechselberger 2010; Koper 1995; Larter and Steinmetz 1991) in addition to the canard phenomenon (Szmolyan and Wechselberger 2001; Wechselberger 2005; Brøns et al. 2006; Rotstein et al. 2006) and the slow passage through a Hopf bifurcation (Larter et al. 1988; Holden and Erneux 1993; Baer et al. 1989) . These mechanisms are reviewed in (Desroches et al. 2012).

We note that MMOs have also been observed in other fields including chemistry and biology (Petrov et al. 1992; Aguda et al. 1989; Hauser and Olsen 1996; Strizhak et al. 2002; Baba and Krischer 2008). In these cases MMOs consists of an alternation of small amplitude oscillations (SAOs) and large amplitude oscillations (LAOs) where the amplitude between SAOs and LAOs differ roughly by an order of magnitude.

Figure Legends

Figure 1. MMO patterns in a 2D STO-F mode with linear subthreshold dynamics (see also resonate-and-fire models (Izhikevich 2001)). The subthreshold dynamics and governed by the following two equations describing the dynamics of the rescaled voltage $V$ (mV) and gating variable $w$ (mV) (see (Richardson et al. 2003)): (i) $CdV/dt = -gL V - gw + I_{app}$, and (ii) $\tau dw/dt = v - w$. Spikes are added manually when $V$ reaches $V_{th}$ and $V$ and $w$ are reset to $V_{rst}$ and $w_{rst}$ respectively. A. The reset values $V_{rst}$ and $w_{rst}$ are constant and independent of the number of spikes. A1. $I_{app} = -0.2$. A2. $I_{app} = 0$. A3. $I_{app} = 0.2$. We used the following parameter values: $C = 1$, $gL = -0.03$, $gI = 0.3$, $\tau = 40$, $V_{th} = 10$, $V_{rst} = -5$, $w_{rst} = -1$. Units are as in (Richardson et al. 2003; Rotstein 2013). B. The reset value $w_{rst}$ changes according to the number of consecutive spikes ($N$) according to the following rule: when $N = N_{max}$, $w_{rst}$ is decreased by an amount $\Delta_{w_{rst}}$. (The reset value $V_{rst}$ is constant and independent of the number of spikes.) B1. $N_{max} = 2$ and $\Delta_{w_{rst}} = 1.5$. B2. $N_{max} = 2$ and $\Delta_{w_{rst}} = 2.5$. B3. $N_{max} = 2$ and $\Delta_{w_{rst}} = 3$. B4. $N_{max} = 3$ and $\Delta_{w_{rst}} = 2.1$. B5. $N_{max} = 3$ and $\Delta_{w_{rst}} = 2.7$. C. The reset values $V_{rst}$ and $w_{rst}$ are constant and independent of the number of spikes (as in A). $I_{app} = -0.2 + \sqrt{2D} \eta(t)$ where last term is white noise (delta correlated) with zero mean and standard deviation $D$. We used $D = 0.2$. Other parameter values are as in A.

Figure 2. MMO patterns in 3D parabolic STO-F models with a parabolic nonlinearity in the voltage equation. The subthreshold dynamics is governed by the following three equations describing the dynamics of the rescaled voltage $V$ (mv) and gating variables $w$ and $z$: (i) $dV/dt = V^2 - w + I_{app}$, (ii) $\tau dw/dt = 0.5 V - w$, and (iii) $\tau dz/dt = \eta$ (panels A) and $\tau dz/dt = \eta(0.5 V +
0.02 − z) (panels B). The onset of spikes is described by the equations describing the subthreshold dynamics. The occurrence of spikes is indicated when \( V \) reaches \( V_{th} \) and \( V, w \) and \( z \) are reset to \( V_{rst}, w_{rst} \) and \( z_{rst} \) respectively. For \( \eta = 0 \), the corresponding 2D systems display damped STOs. **A1:** \( I_{app} = −0.008 \). **A2:** \( I_{app} = −0.006 \). **A3:** \( I_{app} = −0.004 \). **B1:** \( I_{app} = −0.004 \). **B2:** \( I_{app} = −0.003 \). **B3:** \( I_{app} = −0.0027 \). **B1:** \( \gamma = 0.04 \). **B2:** \( \gamma = 0.06 \). **B3:** \( \gamma = 0.08 \). We used the following parameters: \( \tau = 100 \), \( \eta = 0.003 \) (A), \( \eta = 0.1 \) (B), \( V_{th} = 1 \), \( V_{rst} = −0.1 \), \( w_{rst} = V_{rst}^2 + I_{app} − 0.001 \), and \( z_{rst} = 0 \).

**Figure 3. STOs, spiking and MMOs in models of FitzHugh-Nagumo type.** A. STOs (\( \lambda = 0.0075 \)), and B. spiking (\( \lambda = 0.008 \)) for the 2D FHN model described by the following equations: (i) \( dv/dt = −2v^3 + 3v^2 − w \), (ii) \( dw/dt = 0.01 \left( 4v − \lambda − w \right) \). C. MMOs for the extended, 3D FHN model described by the following equations: (i) \( dv/dt = −2v^3 + 3v^2 − w \), (ii) \( dw/dt = 0.01 \left( 4v + 0.02 − z − w \right) \), (iii) \( dz/dt = 0.0005 \left( 4v + 0.9 − z \right) \). Left panels: voltage time courses. Middle and right panels: Phase-planes. The right panels are magnifications of the middle ones. Panel C3 corresponds to the projection of the phase-space (for the variables \( v, w \) and \( z \)) onto the \( v-w \) plane.
